

00 A SHARED VOCABULARY, EXTRACTED —

CompanyGraph.

The meta-model for operating a company.

An introduction · a talk by Robert Blust

A company's knowledge lives everywhere — and nowhere.

Purpose, strategy, processes, roles, metrics, rules — scattered across wiki pages, spreadsheets, tickets, chat threads and people's heads.

Neither people nor agents can rely on it. What if all of it were one graph a machine could read?

Two companies. The same shape.

ONE WITH A PAYROLL

A deliberately thin file per person.

The rest of a person's story lives on a public website.

ONE COMPANY OF ONE

Forced to model a person properly.

That is where **profile**, **skill** and **experience** come from.

Neither knew about the other. Both ended up here:

One file per entity

one Markdown file

Frontmatter and a body

facts and prose together

Folders named for the type

the type is where it lives

Schemas in their own folder

beside the facts, not inside them

A shape two teams reach independently is evidence — not a preference.

One file per entity.

Frontmatter and a body

the facts for the machine, the prose for the person

A file while it owns nothing

a folder as soon as it owns collections of its own

The H1 is the name

not a field in the frontmatter, not the filename

Everything cross-references — no dead links.

References are names — the canonical name of the entity, never a path.

Moving breaks nothing — nothing pointed at where the file was.

Renaming breaks loudly — a name that does not resolve is caught, not shipped.

No dead links — because there are no links.

Everything that makes a company — in one vocabulary.

profile

who someone is

role

who does what

process

how work flows, gate by gate

rule

what we enforce

kpi

what we measure

concept

what we define

Versioned like code, reviewed like code — **one vocabulary for all of it.**

Governance as data — not as a slide.

Who signs it off

a named role — if it is vacant, there is no sign-off

The criterion

the proposal names the rules it touches

The rule behind it

nothing gets built before the gate is signed off

What stops the work again

written with the proposal, not afterwards

It pays twice — for people, and for agents.

FOR PEOPLE

Onboarding by role. An answer to “who owns this?”

And one place where the answer is the same for everyone.

One source — two audiences, and no drift between them.

FOR AGENTS

A context layer they can act inside.

Vision, strategy, process, rules — stated, not inferred.

Markdown. Checked by agents.

The schemas are Markdown too — a table per type, in the same repository as the facts.

Written to a fixed shape — the same columns, the same type words, the same word for required.

Not a stage on the way to JSON Schema — a formal schema language would make the model something only a tool can read.

It shrinks the space an agent has to guess in — and states the guardrails.

Copy it into a repository of your own.

Nothing to install, nothing to run. A folder of Markdown files and the conventions that hold them together as one graph.

| Not all of it is written yet — the roadmap says what is.
