

00 COMPANYGRAPH, DESCRIBED IN COMPANYGRAPH —

CompanyGraph explains its own Obsidian plugin

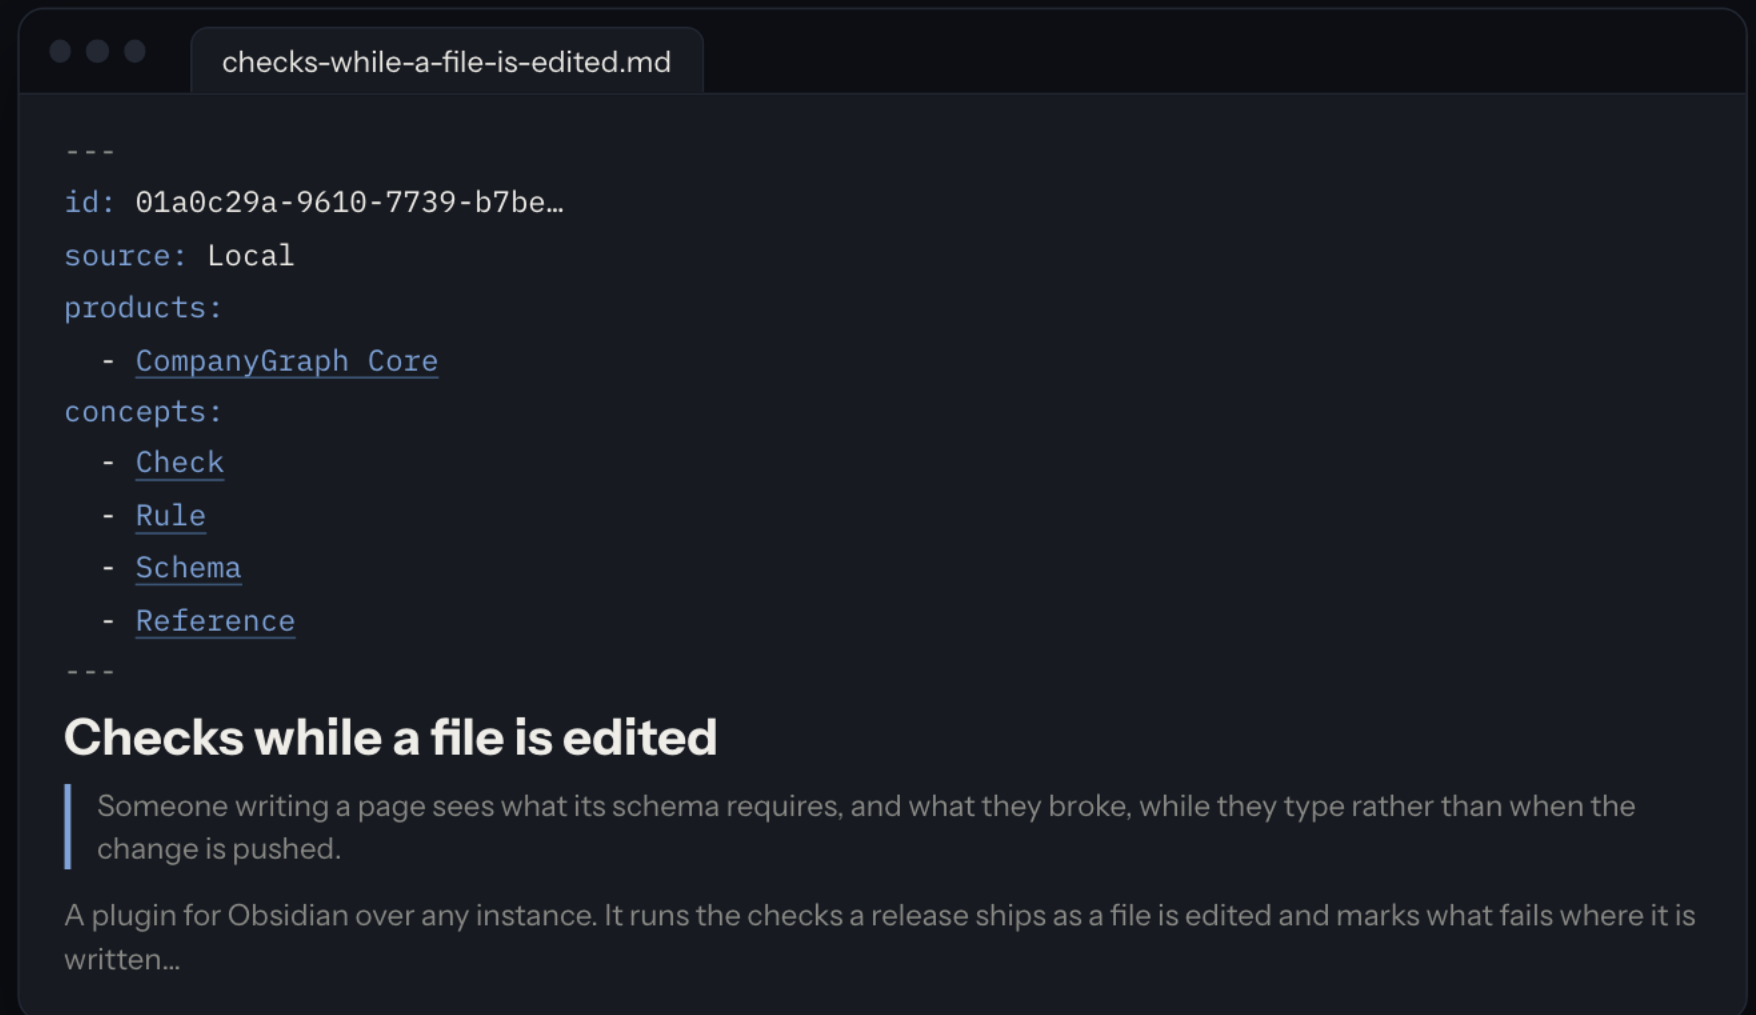

Every pane and every feature, read from the model it edits.

Robert Blust · Software Engineer & Architect

The plugin has a page in the model it edits

CompanyGraph describes itself in CompanyGraph. The plugin is one feature of the product CompanyGraph Core, and this is its page as the repository holds it.

Its concepts are this talk's vocabulary.

```

Checks while a file is edited

Someone writing a page sees what its schema requires, and what they broke, while they type rather than when the change is pushed.

A plugin for Obsidian over any instance. It runs the checks a release ships as a file is edited and marks what fails where it is written...

An instance is a folder of Markdown files. So is a vault.

What a vault lacks is what an instance's CI supplies after the edit: a reference that resolves, and no field its schema does not declare. The plugin says so while the edit is made, and implements no rule of its own.

RESTS ON `concept Instance` `concept Core` `concept Check` `decision Core is vendored into an instance at a release its manifest names`

Where each part sits in Obsidian

The editor

Failures marked on their line, completion from the schema, names that open what they name, held headings, a picture at the H1.

Meta-model compliance

Every failure in the instance, by file.

References

What names this entity, and what it names.

The status bar

The failure count, and the pin when it differs.

Writing brief

What the schema says of the place the cursor is in.

A failure is marked where it is written

Every change checks the whole model, because a reference crosses files. A failure gets a mark on its line, a row in the pane and a count in the status bar.

Copy report puts the pane on the clipboard, for an agent or an issue.

by names "Architect", and no role has that name

Copy report

● CompanyGraph: 1 failure

What names an entity, and what it names

The pane follows the note in front. Each entry says where the name stands, a field or a section and its column, and opens that line.

While a vault is an instance, Obsidian's backlinks, outgoing links, properties and tags panes are off: none of them knows a name a schema declares.

The schema's rules, where the writing happens

The brief follows the cursor. It names the place, says whether the schema requires it, and shows the rules that name it.

A section or field in a rule is a chip that moves the cursor there. The type's other rules fold under the place each one names first.

● CompanyGraph: complies

It offers what the schema declares, and only that

A reference field offers the canonical names of its type, an enum its permitted values, a table cell what its column declares.

A name resolves by the type its schema declares; a name that exists only under another type is not offered.

RESTS ON concept Schema concept Canonical name

decision A reference resolves by its declared type, never by name alone

A company we have never met keeps its own model

A company keeps its model with whichever agent it chooses

Every gate an agent's work passes is held by a person

Core holds a company without running out of vocabulary

CompanyGraph: complies

Add property knows the schema

In Live Preview, Add property lists exactly the fields this file's schema declares and the file lacks, the required ones first.

Its last entry hands over to Obsidian's own list, for a field the checks will then report.

RESTS ON concept Schema

decision A section is open and a field is closed

CompanyGraph: 1 failure

A declared name reads as a link

A name a schema declares is drawn as a link, and one that names nothing as an unresolved link. Cmd-click opens the entity it names.

The model's edges reach Obsidian's graph view, so an entity's neighbors there are the ones the model names.

RESTS ON `concept Reference`

```

No decision has this name.

CompanyGraph: 1 failure

Declared headings are held, a missing one is drawn

A required section the page lacks is drawn where the schema puts it, and one click writes it. Add a section and Remove section do the rest.

A heading the schema declares is held against a stray edit. A section of the page's own is allowed.

RESTS ON concept Schema

decision A section is open and a field is closed

An instance is made and moved from Obsidian

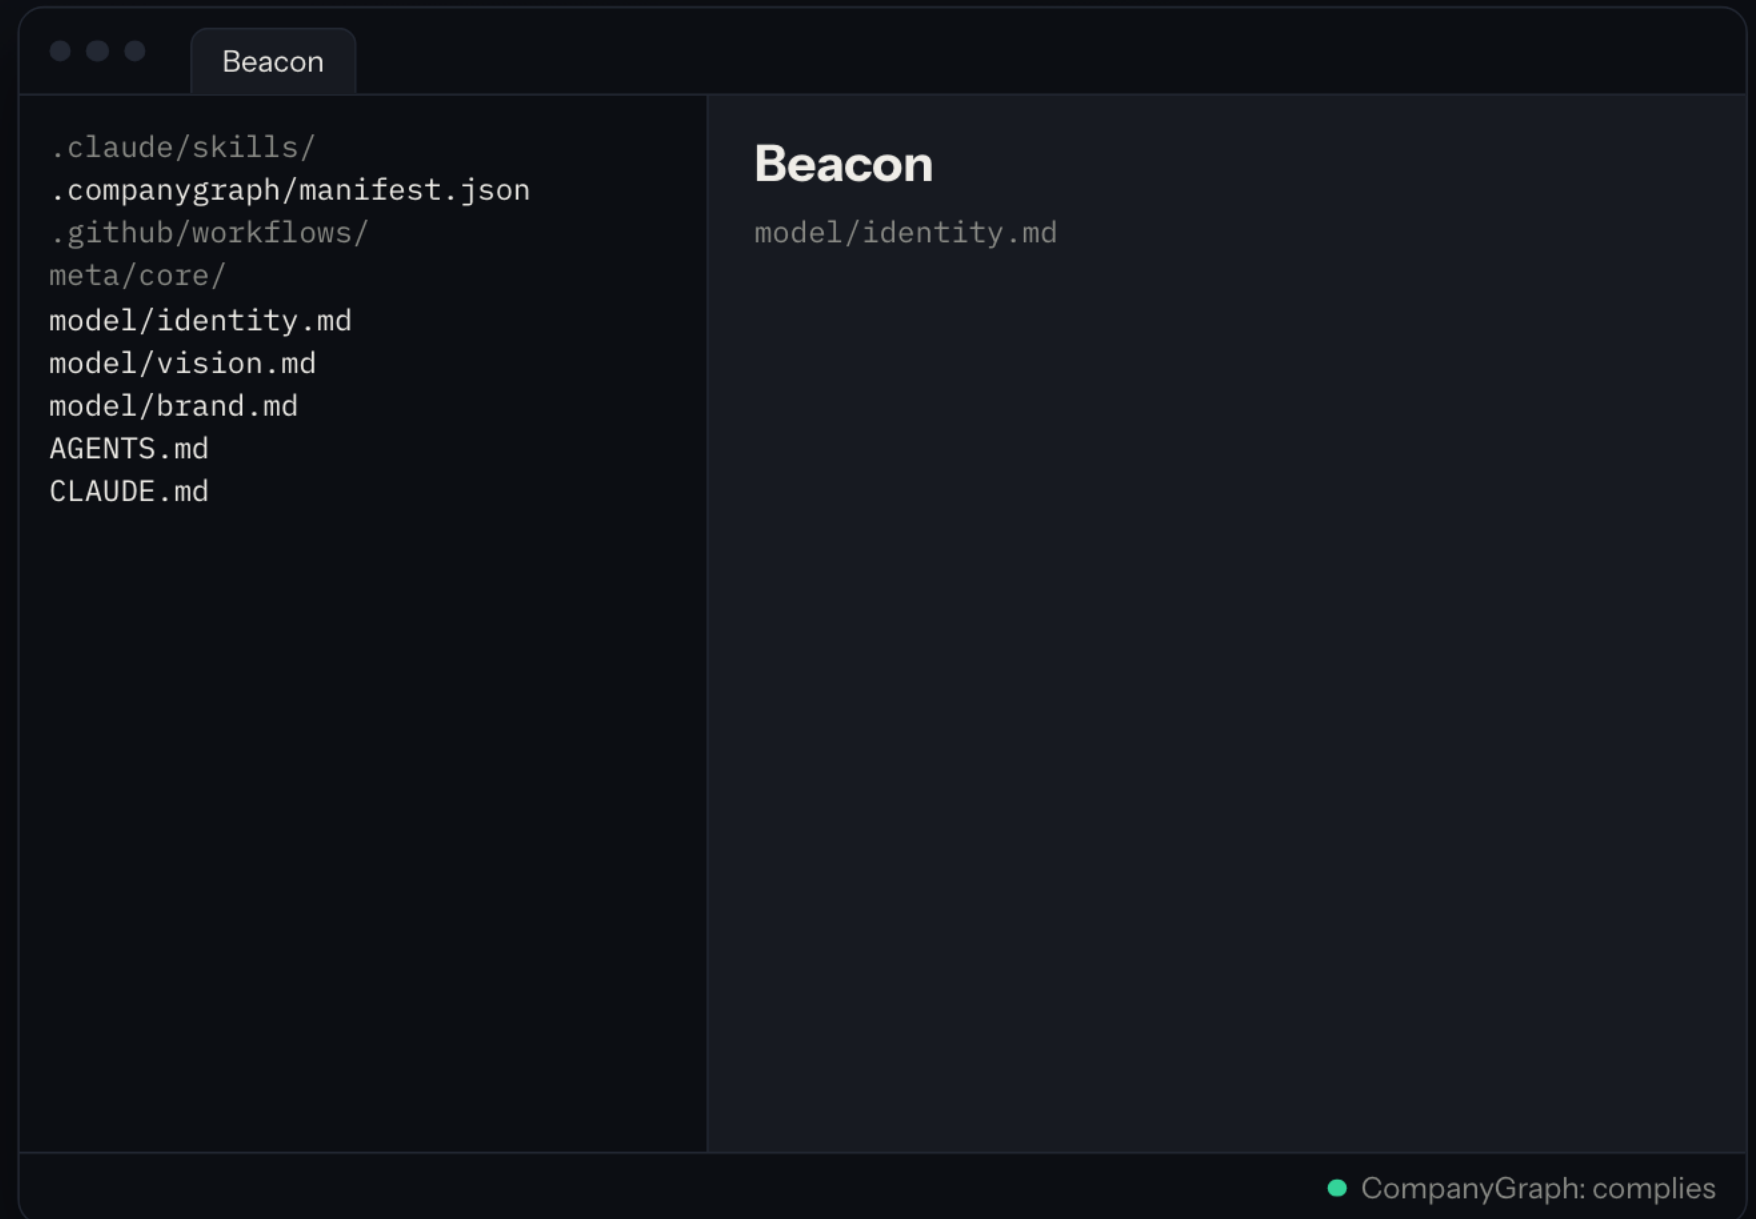

Make this vault an instance writes core, the manifest, CI and the first entities. Move this vault's core takes a newer release and leaves the model alone.

Open the command line opens the meta-model's own, in a tab at the vault's root.

RESTS ON feature An instance is made and kept from one command

concept Core

concept Pin

A note is written back in the one Markdown form

Obsidian's table editor pads every column the moment one cell is edited. The plugin writes the note back in the form the CI checks, when it is left or saved.

An edit that was undone leaves no diff at all.

RESTS ON

concept Rule

2026-vendored-core.md

Bears on

Written back in the form when the note was left

Type Entity Owner How
--- --- --- ---
concept Core changed it
concept Pin made it
concept Instance changed it

git: no change

Four smaller things it does

A picture at the H1

A profile's picture is drawn round at the start of its heading. One that is not square, is outside 256 to 1024 pixels or is over 300 KB fails by name.

The pin, in the status bar

It says pin differs when the manifest names another checker release than the one bundled. The instance's CI stays the gate.

A failing row, tinted

In a Live Preview table, a row that fails is tinted, with its message as the tooltip.

A question's Rests on

Each row reads its type and owner from its own cells, as the checks do, and completes within them.

All of it is in the command palette

Writing

- Complete here
- Add a field
- Add a section
- Remove section
- Open the writing brief
- Write this note in the Markdown form

Checks

- Open the compliance pane
- Check compliance now

Entities

- New entity
- Rename entity
- Delete entity
- Copy entity id
- Give this page a fresh id

References

- Open the references pane
- Toggle references in document

The instance

- Make this vault an instance
- Move this vault's core
- Open the command line

Obsidian's own, off in an instance

- Backlinks
- Outgoing links
- Properties
- Tags

It stops at the editor.

The gate a change has to pass is still the checks an instance runs in CI. And the writing rules are a judgment: no check reads them, here or anywhere. The brief puts them where the writing happens, and a person holds a page to them.

RESTS ON `concept Rule` `objective Every gate an agent's work passes is held by a person`

The meta-model's tooling installs it

```
npx --yes 'github:companygraph/meta-model#semver:*'
```

Its menu's Obsidian plugin entry puts the newest release into the vault and switches it on. Run again, it updates the plugin and keeps its settings. The plugin is not in Obsidian's community directory.

RESTS ON `decision` A release is its tag, and nothing we make is published to a registry `feature` An instance is made and kept from one command
